(54) Title: PORTABLE DEVICE AND METHOD OF COMMUNICATING MEDICAL DATA INFORMATION

(57) Abstract: This invention relates to a portable medical device for communication of medical data information comprising a medical device part comprising a first processor and first storage means, and means for executing one or more medical related functions, a communication device part comprising a second processor, second storage means, and communication means, where the medical device part and the communication device part is connected allowing for exchange of data information according to a predetermined protocol, where the exchange of communication is under the control of the medical device part and where the functionalities of each device part otherwise is separated. Additionally, the invention relates to a method of communication of medical data information.

TR), OAPI patent (BF, BJ, CF, CG, CI, CM, GA, GN, GQ, GW, ML, MR, NE, SN, TD, TG).

Portable device and method of communicating medical data information.

5 The present invention relates to a portable medical device for communication of medical data information.

The present invention also relates to a method of communication of medical data information by a portable medical device.

10

Product and software validation for medical products are troublesome, delays a product's time-to-market, time-consuming, complicates revision tasks, and is expensive.

15 Rapid development in the field of communication requires for frequent updates of communication soft-, hard- and/or firmware in a medical device. As a result medical product and software validation is required for a medical device with updated communication means even though no changes
20 have been made to the medical application "part" of the device.

An object of the present invention is to provide a device that avoids the need for further medical product and
25 software validation when the communication part of a medical device is changed, updated, revised etc.

Another object is to clearly separate the critical medical application functionalities from the complex
30 communication software, hardware and/or firmware in order to obtain maximum safety and reliability of the critical medical application.

These objects among others are achieved by a device of the aforementioned kind that comprises

- a medical device part
 - o comprising a first processor and first storage means, and
 - o means for executing one or more medical related functions,
- a communication device part
 - o comprising a second processor, second storage means, and
 - o communication means,

where the medical device part and the communication device part is connected allowing for exchange of data information according to a predetermined protocol, the exchange of data information is under the control of the medical device part and where the functionalities of each device part otherwise is separated.

Hereby, two physically and functionally separated parts/units are obtained where one part is a medical device part responsible for performing medically related actions, measurements, calculations, exchange of data with other medical devices, etc. and another part is a communication device part (just communication part in the following) responsible for receiving and transmitting information under the control of the medical device. The medical device part controls the communication so the communication part cannot interrupt or request service(s) from the medical device part, thereby ensuring maximum safety and reliability of the medical application(s).

In this way, when the parts (software, hardware, firmware, etc.) of the communication device needs to be upgraded, the integrity of the medical device part is

preserved and the need for any further medical product and software validation is avoided thereby reducing time-to-market, expenses, etc.

5 Furthermore, when changes to the medical device part hardware, software, and/or firmware are required then the scope of medical product and software validation can be restricted to the medical device part and need not involve the communication device part thereby simplifying
10 revisions tasks, etc.

According to a preferred embodiment, the predetermined protocol comprises the medical device part acting as a master and the communication device part acting as a
15 slave where the exchange of information is done by the medical device part polling the communication device part.

In this way, a simple protocol may handle and connect the
20 two asynchronous systems/parts of the medical device in a very simple fashion and the communication part cannot interfere, interrupt and/or transmit data/information to the medical part without its permission.

25 In one embodiment, the medical device part further comprises one or more of:

- a user interface,
- at least one medical transducer,
- discrete and/or substantially continuously body
30 fluid analysis means,
- drug administration means, and
- a short-range communication means for exchanging data information with at least another medical device.

In this way, relevant medical functions, like blood glucose/body fluid level measurement(s), drug or insulin administration, may be integrated directly with the medical device, so that a user will always have a medical function ready at hand when using the medical device thereby avoiding the need for an extra medical device. Additionally, the medical device may act as a data collection/exchange device collecting/exchanging data with other relevant medical devices using short-range communication.

In one embodiment, the at least another medical device is selected from the group of:

- a drug administration device,
- a body fluid analyser,
- an insulin administration device,
- a blood glucose monitor (BGM),
- a continuous blood glucose monitor (CGM)
- an inhaler,
- a tablet dispenser,
- a lipid monitor,
- a pulse monitor,
- a lancet device,
- a storage container,
- a balance,
- and any other apparatus adapted to measure at least one physiological parameter.

In one embodiment, the device further comprises a power supply supplying the communication device part with power where the power supply may be turned on and off under the control of the medical device part.

In this way, power usage may be saved/minimized by turning the communication part off when it is not used which is especially important for portable devices usually having a limited power supply.

5

In one embodiment, the communication means is adapted to communicate according to the Bluetooth protocol.

Hereby, a very simple way of connecting to other devices
10 and/or networks are obtained.

In one embodiment, the communication means are adapted to communicate information according to one or more of:

- Radio frequency (RF) communication,
- 15 • Infrared (IR) communication,
- HTTP (Hyper Text Transmission Protocol),
- SHTTP (Secure Hyper Text Transmission Protocol),
- TCP/IP (Transmission Control Protocol/Internet Protocol),
- 20 • PPP (Point-to-Point),
- SSL (Secure Socket Layer),
- TLS (Transport Layer Security), and
- IrDA,

25 In one embodiment, the communication means are adapted to communicate with a wireless access point/a mobile terminal where the access point/the terminal is adapted to communicate according to one or more of:

- GSM (Global System for Mobile communication),
- 30 • GPRS (General Packet Radio System), and
- UMTS (Universal Mobile Telephone System).

In this way, a great level of mobility is assured for the user of the medical device as well as being able to transmit relevant data information.

- 5 In one embodiment, the communication device part is adapted to exchange data information with a central server via a wireless network access point.

The invention also relates to a system for supplying data
10 from a portable medical device to a third party, where the system is adapted to

- automatically transmit data information from a portable medical device to a central server for storage in at least one database,
- 15 • process said data information, in order to derive additional information, and
- automatically transmit at least a part of the additional information to a predetermined third party.

20

In this way, a relative/relatives may obtain an ease at mind since they know that they will receive information if anything is wrong or may be potentially dangerous or they simply is automatically updated on the user's
25 current situation. This is especially useful for relatives of elderly people, children, etc. using a medical device. A medical professional may also receive relevant information in this manner.

- 30 In one embodiment, the processing is done at said server and/or at said medical device.

In one embodiment, the data information comprises information representing one or more of:

- at least one blood glucose value,
- at least one value representing a body fluid level,
- at least one physiological parameter,
- amount and/or type of administered medication,
- 5 • amount and/or type of administered insulin,
- a trend of a glucose or body fluid level,
- a prediction of a glucose or body fluid level,
- timestamp in- or excluding date,
- amount of food,
- 10 • measurement of physical activity,
- notification of appointment,
- inventory logistics, and
- body characteristics.
- warnings, and
- 15 • symptoms.

In one embodiment, the system is adapted to transmit data information from a portable medical device to a central server according to the Bluetooth protocol using a
20 wireless access point connected via a network to the central server.

In one embodiment, the third parties are one or more of:

- at least one relative,
- 25 • at least one parent, and
- at least one medical professional.

In one embodiment, the system is further adapted to
• exchange information between the portable medical
30 device and another medical device in order to retrieve relevant data information.

The invention also relates to a system for collecting data information from a number of portable devices, where the system is adapted to:

- generate data information in a portable device, the
5 data information relating to a clinical trial of a medical device and/or medical product,
- automatically sending the data information from the portable device to a central server for storage in a database,
- 10 • process said data information.

In this way, relevant information may then be automatically transmitted directly to a relevant server for high-quality data storage and collection since the
15 actual obtained data is obtained directly from the user/patient and transmitted e.g. for further processing. This may reduce the cost and the time-to-market of a new product since the data collection from many medical devices taking part in the medical trial may be
20 automated. Additionally, the need for hand-written logs of the participants of the trial is avoided thereby eliminating possible typos and avoiding the need for manually inputting/scanning the logs into a system for storage and processing.

25

The invention also relates to a method of communication of medical data information between a medical device part

- o comprising a first processor and first storage means, and
 - 30 o means for executing one or more medical related functions,
- and a communication device part
- o comprising a second processor, second storage means, and

o communication means,
where the medical device part and the communication
device part exchanges data information according to a
predetermined protocol, the exchange of data information
5 is under the control of the medical device part and where
the functionalities of each device part otherwise is
separated.

In one embodiment, the predetermined protocol comprises
10 the medical device part acting as a master and the
communication device part acting as a slave where the
exchange of information is done by the medical device
part polling the communication device part.

15 In one embodiment, the medical device part further
comprises one or more of:

- a user interface,
- at least one medical transducer,
- discrete and/or substantially continuously body
20 fluid analysis means,
- drug administration means, and
- a short-range communication means for exchanging
data information with at least another medical
device.

25

In one embodiment, the at least another medical device is
selected from the group of:

- a drug administration device,
- a body fluid analyser,
- 30 • an insulin administration device,
- a blood glucose monitor (BGM),
- a continuous blood glucose monitor (CGM),
- an inhaler,
- a tablet dispenser,

- a lipid monitor,
- a pulse monitor,
- a lancet device,
- a storage container,
- 5 • a balance,
- and any other apparatus adapted to measure at least one physiological parameter.

10 In one embodiment, the method further comprises controlling a power supply by the medical device part, where the power supply supplies the communication device part with power.

15 In one embodiment, said communication means communicates according to the Bluetooth protocol.

In one embodiment, said communication means communicates information according to one or more of:

- Radio frequency (RF) communication,
- 20 • Infrared (IR) communication,
- HTTP (Hyper Text Transmission Protocol),
- SHTTP (Secure Hyper Text Transmission Protocol),
- TCP/IP (Transmission Control Protocol/Internet Protocol),
- 25 • PPP (Point-to-Point),
- SSL (Secure Socket Layer),
- TLS (Transport Layer Security), and
- IrDA,

30 In one embodiment, said communication means communicates with a wireless access point/a mobile terminal where the access point/the terminal communicates according to one or more of:

- GSM (Global System for Mobile communication),

- GPRS (General Packet Radio System), and
- UMTS (Universal Mobile Telephone System).

In one embodiment, the communication device part
5 exchanges data information with a central server via a wireless network access point.

The invention also relates to a method of supplying data from a portable medical device to a third party, the
10 method comprising the steps of:

- automatically transmitting data information from a portable medical device to a central server for storage in at least one database,
- processing said data information, in order to derive
15 additional information, and
- automatically transmitting at least a part of the additional information to a predetermined third party .

20 In one embodiment, said processing is done at said server and/or at said medical device.

In one embodiment, said data information comprises information representing one or more of:

- 25 • at least one blood glucose value,
- at least one value representing a body fluid level,
- at least one physiological parameter,
- amount and/or type of administered medication,
- amount and/or type of administered insulin,
- 30 • a trend of a glucose or body fluid level,
- a prediction of a glucose or body fluid level,
- timestamp in- or excluding date,
- amount of food,
- measurement of physical activity,

- notification of appointment,
- inventory logistics, and
- body characteristics.
- warnings, and
- 5 • symptoms.

In one embodiment, said step of transmitting data information from a portable medical device to a central server is done by transmitting said data information
10 according to the Bluetooth protocol using a wireless access point connected via a network to the central server.

- In one embodiment, said third parties are one or more of:
- 15 • at least one relative,
 - at least one parent, and
 - at least one medical professional.

- In one embodiment, said method further comprises the step
20 of:
- communicating between the portable medical device and another medical device in order to retrieve relevant data information.

- 25 Finally, the invention also relates to a method of collecting data information from a number of portable devices, the method comprising the steps of:
- generating data information in a portable device, the data information relating to a clinical trial of
30 a predetermined medical product and/or device,
 - automatically sending the data information from the portable device to a central server for storage in a database,
 - processing said data information.

The method and embodiments thereof correspond to the device and embodiments thereof and have the same advantages for the same reasons, and therefore will not
5 be described again.

The present invention will now be described more fully with reference to the drawings, in which

10 Figure 1 shows a schematic block diagram of a medical device according to the present invention;

Figure 2 shows a more detailed schematic block diagram of a medical device comprising a Bluetooth communication
15 device part;

Figure 3 illustrates the communication between a medical device part and a Bluetooth communication device part;

20 Figure 4a and 4b illustrates examples of the communication between a medical device and other devices according to the present invention;

Figure 5 illustrates the communication between a
25 Bluetooth communication device part and a central Internet server;

Figure 6a illustrates the short-range communication between a medical device according to the present
30 invention and other medical devices;

Figure 6b illustrates communication between a medical device according to the present invention and other medical devices;

Figures 7a - 7c illustrate examples of various embodiments of the short-range communication means.

5 Figure 1 shows a schematic block diagram of a medical device according to the present invention. Shown is a medical device (100) comprising an integrated medical device part (101) (denoted medical part in the following) and an integrated communication device part (102)
10 (denoted communication part in the following).

The medical part (101) comprises one or more first microprocessors/processing means (104), a first storage/storage means/memory means (103), and means for
15 providing/performing medical related functionalities (106) like medically related actions, measurements, calculations, etc.

The means for providing medical functionalities (106) may
20 e.g. comprise one or more of body fluid analyser means, drug administration means, and/or short-range communication means for communicating with at least another medical device and may operate under the control of a separate processor (not shown), again being
25 controlled by the first processor (104), or under the control of the first processor (104) directly.

The communication part (102) comprises one or more second microprocessors/processing means (104'), a second
30 storage/storage means/memory means (103'), and communication means (105) for communicating with and/or via other devices.

The medical part (101) and the communication part (102) are connected allowing for exchange of data between them via a physical interface (like a simple electrical connection) where the exchange of data happens according to an interface layer (107) located in and under the control of the processor (104). The interface layer (107) comprises a suitable protocol and is under the complete control of the processor (104) of the medical part (101). A suitable protocol may e.g. be a protocol where the medical part (101) operates as a master and the communication part (102) operates as a slave as indicated by the one-way arrow (109) (even though exchange of information is allowed in both directions). In this way, two physically and functionally separated parts/units (101; 102) are obtained as indicated by the line (108) where a medical part (101) is responsible for performing medically related actions, measurements, calculations, etc. and another part (102) is a communication part responsible for receiving and transmitting information under the control of the medical device. Hereby, the critical medical application functionalities is clearly separated from the complex communication software, hardware and/or firmware giving maximum safety and reliability of the critical medical application.

Preferably, the medical device (100) further comprises a user interface (not shown) for receiving and/or presenting information from/to a user of the medical device (100). The user interface preferably comprises input means like buttons, scroll-wheels or the like and output means like a display or combined input-output means like a touch sensitive display like already known in the art.

The first and second storage/memory means (103; 103') may e.g. be a non-volatile memory, a volatile memory or a combination of both. Examples are flash memory, RAM, ROM, EEPROM, magnetic and/or optic storage means, etc.

5

The first (104) and second (104') processing means/processors may comprise one or more general or special purpose micro-processors or a mix hereof.

10 The communication means (105) preferably communicates according to the Bluetooth standard/protocol. Alternatively, communication via RF, IR, a wire/cable is used according to a suitable protocol.

15 Figure 2 shows a more detailed schematic block diagram of a medical device comprising a Bluetooth communication part. Shown is a medical part (101) and a communication part (102) corresponding to the one shown in Figure 1.

20 The communication part (102) comprises a Bluetooth communication core and is adapted to communicate with external devices according to the well-known Bluetooth protocol. The Bluetooth core/the Bluetooth protocol stack comprises an Interface Layer interfacing with the medical
25 part (101). The Interface Layer comprises in one embodiment an XML Glue-layer for generating, providing, handling, etc. XML scripts thereby allowing for a receiver to handle/execute these scripts directly. The protocol stack of the communication part (102) also
30 comprises the TCP/IP (Transmission Control Protocol/Internet Protocol) and PPP (Point-to-Point Protocol) protocols connected to the Interface Layer via the XML Glue-layer. An RFComm (a serial emulation protocol) manager is connected to the TCP/IP/PPP protocol

manager. The Bluetooth Core also comprises a Service
Discovery Protocol (SDP) manager that is responsible to
determine which services are available from Bluetooth
enabled service servers like a PC or a mobile telephone
5 offering services like Internet and/or Network
connection, etc. or other types of services. The SDP
manager is also connected to the Interface Layer. Both
the SDP and the RFCOMM manager are connected to a L2CAP
(Logical Link Control and Adaption Protocol) manager
10 (responsible for channel establishment) that is connected
to a Link Manager (LM) (responsible for link
establishment). The Bluetooth Core also comprises a
Baseband and a Bluetooth Radio specification responsible
for the radio communication according to the Bluetooth
15 specification. Information regarding the Bluetooth
protocol may e.g. be obtained at www.bluetooth.com
incorporated herein by reference.

The communication steps between the medical device part
20 (101) and a communication part (102) using Bluetooth are
explained in greater detail in connection with Figure 3.

The medical part (101) comprises a user interface for
receiving and/or presenting information from/to a user of
25 the medical device in the form of input means (202) like
buttons, scroll-wheels, etc. and output means like a
display (201) or combined input-output means like a touch
sensitive display as signified by the double arrow in
parenthesis. The medical part (101) also comprises a
30 memory (103) for storing software, firmware, relevant
data/information, etc. The medical part also comprises a
real-time clock (RTS) (110) for enabling time- and date-
stamps of generated/provided information like time-

stamping a glucose/body fluid level measurement, a drug/insulin administration, etc.

Furthermore, the medical part (103) comprises one or more
5 medical function(s) (106) like described in connection
with Figure 1. In this particular embodiment the medical
device part (101) comprises an integrated medical
transducer or a medical potentiostat like a body fluid
analyser or more particularly a BGM (blood glucose
10 monitor), either a continuous (CGM) or a discrete
monitor. An additional medical function in this
particular embodiment is (e.g. very) short-range
communication means (106') so that the medical device
part (101) may communicate with another medical device
15 (405), like a drug administration unit, an insulin pen,
an insulin doser, an inhaler, tablet dispenser, etc., in
a very simple manner thereby allowing exchange of
relevant information/data like type and amount/dose of
administered medication and a corresponding time/date-
20 stamps. The information may e.g. be generated during use
of the other medical device(s) and stored there until
transferred to the medical part (101). These short-range
communication means may e.g. be optically communication
means like a Infrared transmitter/receiver pair (106')
25 where communication is initiated automatically when the
additional medical device is docked with or fitted to the
medical communication device (100) or simply is in close
proximity. Alternative short-range communications means
are inductive or electronic communications means that are
30 explained in greater detail in connection with Figures 7a
- 7c.

Alternatively, the communication part (102) may be used
to exchange information with other medical devices (405)

thereby avoiding the need for short-range communications means (106'), however the short-range communications means (106') would typically require less power and allows for simple, easy and transparent, for the user,
5 (if communication is initiated when docking the device) exchange of information.

The medical device part (101) and communication part (102) are separated like described before and signified
10 by the line (108) and connected allowing only for exchange of data under the strict control (as signified by the one-way arrow (109)) of the medical device part (101).

15 The medical device preferably also comprises a power supply (203) to the communication part (102) that is controlled by the medical device part (101). In this way, the communication part (102) may be turned off in order to conserve power.

20 Figure 3 illustrates the communication between a medical part and a Bluetooth communication part. Shown are the communication steps between the medical device part (101) and the communication device part (102).

25 The medical device part (101) comprises an application layer, a Medicom Layer (corresponds to (106) in Figs. 1 and 2) and an Interface Layer (corresponds to (107) in Fig. 1). The medical device part (101) comprises the
30 Bluetooth core shown and described in connection with Figure 2.

Communication may e.g. be initiated either on user request, request by a medical application in the medical

device part (101) (e.g. on the basis of an obtained measurement from an integrated medical transducer), an internal request by the medical device (100), by docking another medical device with the medical device (100) and/or using short-range communication means (106') with an additional medical device like a doser, a CGM, inhaler, a BGM, etc.

When a request for Bluetooth communication via the communication device part (102) is generated, the medical part (101) generates a Bluetooth power-up by activating the power supply (203 in Figure 2) if the communication part (102) is not already powered. Then a request for a Bluetooth link to a relevant information receiver is sent to the communication part (102). The communication part (102) establishes a suitable link and returns an acknowledgement after which the actual communication/transmission of data may begin. If no establishment of a communication link is possible or communication is impossible for another reason, the relevant information is kept and may be tried transmitted at another time, e.g. when the user uses the medical device (100) the next time. Preferably, the communication part (102) is switched off when it is determined that no communication is currently possible in order to conserve power usage. A warning may be presented to the user specifying that communication was not possible, but preferably the communication takes place without the user's specific knowledge and a warning may e.g. only be presented to the user if no data communication was possible after a given number of tries or within a given period of time dependent on the actual application of the medical device (100).

After a Bluetooth link is successfully established, a first frame comprising an amount of data/information is sent to the communication part (102) where the frame is transmitted via the Bluetooth radio transmitter. The communication part (102) reports when the information has been transmitted, i.e. when a frame buffer is empty. The steps 'send frame' and 'report empty buffer' repeats/loops until the complete amount of information has been sent, i.e. N frames of information has been transmitted via Bluetooth radio communication. After the medical part (101) receives a 'frame buffer empty' and no further information has to be sent, the medical part (101) may send a request for receipt of the Bluetooth communication from the communication part (102). The communication part (102) returns a receipt of the Bluetooth communication with the relevant information receiver to the medical device part (101), which then executes a power-down of the communication part (102) in order to conserve power if no additional information is to be exchanged.

The communication between the communication part (102) and a relevant information receiver is explained in connection with Figures 4a, 4b and 5.

Figure 4a and 4b illustrates examples of the communication between a medical device and other devices according to the present invention.

Figure 4a illustrates communication between a medical device (100) and a mobile communications terminal (402) belonging to a relevant third party via a mobile communications terminal/a wireless access point (401), belonging to a user of the medical device (100), to a

network/the Internet. The medical device (100) preferably communicates with the user terminal (401) according to the Bluetooth protocol like described in connection with Figures 2 and 3, thereby establishing a Bluetooth communications link between the communication device part of the medical device (100) and the user's terminal (401). Alternatively, the communication between the medical device (100) and the user's terminal (401) may be done via IR communications means, a cable connecting them, other radio frequency (RF) communications means, etc.

When the Bluetooth communications link is established information may be transmitted to a terminal (402) of a relevant third party using a GSM (Global System for Mobile communication), UMTS (Universal Mobile Telephone System) and/or GPRS (General Packet Radio System) communication network or another wireless communication network, so that relevant information may be exchanged between the user's terminal (401) (and thereby the medical device (100)) and the terminal (402). The information may e.g. be exchanged between the terminal (401) and the terminal (402) using SMS (Short Message Service) or e-mail as a carrier (e.g. sending SMS messages/e-mails alternating in both or in one direction only) or alternatively, a two-way data communication between the terminals (401; 402).

A relevant third party may e.g. be a medical professional, a care-team, etc. and/or a relative of the user.

In this way, a medical professional may, e.g. automatically, receive status reports of the user at a

regular time interval or when dangerous or potentially dangerous situation occurs or is about to occur, e.g. when a critical body fluid/blood glucose level being outside a predetermined interval has been determined and/or estimated (for a future time) by the medical device (100). Additionally, the professional may send relevant information, like an updated medical regime and/or target body fluid/blood glucose level interval, suggested action for a given situation (e.g. administer X amounts of type Y medication) e.g. in response to information/data received from the user's terminal (401)/the medical device (100). This enables a very close and precise monitoring of the user since data/information may be transmitted to a professional regularly in an easy and transparent manner and the data/information may be obtained directly by the medical device (100) and/or other devices (BGM, CGM, insulin doser, drug administration device, body fluid monitor, etc.) in communication and/or integrated with the medical device (100).

A medical professional may also determine when the user has to be called in for a consultation, check-up, etc. based on actual received information instead of having regular consultations. In this way, a user only needs to attend a consultation when there is an actual need. Additionally, the professional is better prepared since the relevant information is available to him in advance of an consultation.

Another application of the present invention is that one or more relatives of the user of the medical device (100) automatically may receive a status report or information from the medical device (100) via the terminal (401)

regarding how the user's situation is and/or going to be in the near future. The transmitted information may e.g. contain time/date, type and/or amount of administered medication, time/date and value of performed measurement(s), compliance with a medical regime, etc. or simply just a status e.g. 'Status is ok', 'possible problem(s)', 'Serious problems', 'X follows the medical regime fully', 'X has a BGL within the target range', etc.

10

In this way, a relative/relatives obtains an easy at mind since they know that they will receive information if anything is wrong or may be potentially dangerous or they simply is automatically updated on the user's current situation. This is especially useful for relatives of elderly people, children, etc. using a medical device (100).

The medical device (100) may also receive and/or transmit relevant data information with one or more external medical related devices (405) as described later in greater detail in connection with Figures 6a and 6b.

Figure 4b illustrates communication between a medical device (100) and a database server (403). The communication between the medical device (100) and the terminal (401) is like described in connection with Figure 4a. Information/data received from the medical device (100) is transmitted by the terminal (401) to a server (403) preferably using the TCP/IP and PPP protocols and GPRS for high-speed data communication. Alternatively, a GSM or a UMTS network may be used. The server (403) may e.g. be an Internet database server. The server (403) receives the relevant information and stores

it and determines what is to happen with the information e.g. where it/a copy is to be transmitted and/or stored, if and how it is to be processed, etc.

- 5 The server (403) may transmit the information to a number of mobile terminals (403) and/or computers (404) e.g. as an SMS message, an e-mail and/or in a suitable data format. Additionally, a computer (404) and/or a terminal (402) may also connect to the server (403) using standard
10 browser software or WAP (Wireless application Protocol) in order to access, retrieve, etc. the relevant stored information, preferably, after specifying a valid password and user-name. In this way, either a client, a relative to a user and/or a medical professional may
15 obtain easy access to the stored historical medical data and/or derivations (e.g. processed) thereof.

The secure socket layer (SSL)/transport layer security (TLS) may also be used by the communication devices in
20 this system (one or more of terminal (401), terminal (402), the medical device (100), the server (403), the computer (404)) in order to enhance the security of the information. Bluetooth incorporates the possibility of using built-in security by finding devices, pairing
25 devices, authentication, and encryption thereby enhancing the security between the medical device (100) and the terminal (401).

Applications of the embodiment shown in Figure 4b
30 corresponds to the applications described above in connection with Figure 4a.

Yet another application of the present invention is that it may be used in connection of a clinical trial of a new

medical product (new/modified drug, new measurement device, new drug administration device). Data collected by the medical device (100) and other related medical devices (405) may then be automatically transmitted
5 directly to the relevant database server (403) for high-quality data storage and collection since the actual obtained data is obtained directly from the user/patient and transmitted e.g. for further processing. This may reduce the cost and the time-to-market of a new product
10 since the data collection from many medical devices taking part in the medical trial may be automated. Additionally, the need for hand-written logs of the participants of the trial is avoided thereby eliminating possible typos and avoiding the need for manually
15 inputting/scanning the logs into a system for storage and processing.

Alternatively, the mobile terminal (401) and/or the mobile terminal (402) may be an electronic device like a
20 laptop,, a PC, a PDA, etc. equipped with communication and/or a gateway (e.g. integrated, a network interface card (NIC), modem, etc.) to the Internet, a cellular network like a GSM, GPRS, UMTS network, etc. or another kind of communications network. The communication between
25 the device (401) and the medical device (100) may e.g. be done via/according to the Bluetooth protocol or another RF communication protocol, IrDA (Infrared Data Association) protocols, a cable connection, etc.

30 One example of the use of the medical device (100) according to the present invention will be illustrated by the following use-case that describes a typical for a diabetic user equipped with a medical device (100) according to the invention.

At 7.00. The user gets out of bed and takes his cap unit with integrated BGM/medical device (100) and measures the
5 glucose content of his blood.

The medical device (100) records this event with a time stamp and saves it in the memory/an electronic log book. Then the medical device (100) searches for a wireless
10 access point (401) to the Internet, and if found, non-replicated data are transferred from the electronic log book to a server.

The user then decides to take x units of actrapid (making
15 ready for his breakfast), he takes an insulin doser/insulin administration device (405) which he has already dedicated to be his actrapid doser and injects x units of actrapid. After the injection the actrapid doser (405) is placed in, docked with, brought in short-range
20 communication range with, etc. the cap unit/medical device (100).

The doser (405) will now make contact to the cap/medical device (100) e.g. by means of an IR diode and an IR
25 transistor to transfer dose size, insulin type, relative time stamp and doser status to the cap.

The cap/medical device (100) transfers setup data, if any, to the doser (405). The cap can now calculate the
30 absolute time of this event and transfers it to the electronic log book.

The medical device (100) now searches for a wireless access point (401) to the Internet, and if found, non-

replicated data are transferred from the electronic log book to a server (403).

At 8.00. The user has his breakfast.

5

At 9.00. The user arrives at his job, he decides (optionally the medical device (100) reminds him) to make a control measurement of the glucose content of his blood.

10

The medical device (100) records this event with a time stamp and saves it in the electronic log-book. The medical device (100) then searches for a wireless access point (401) to the Internet, and if found, non-replicated data are transferred from the electronic log-book to a server (403).

15

At 12.00. The user decides to measure the glucose content of his blood again.

20

The medical device (100) records this event with a time stamp and saves it in the electronic log-book. The medical device (100) then searches for a wireless access point (401) to the Internet, and if such an access point is found, non-replicated data are transferred from the electronic log-book to a server (403).

25

He now decides to take x units of actrapid (making ready for his lunch). After the injection he places his actrapid doser in the cap/medical device (100).

30

The doser (405) will now make contact to the cap/medical device (100) by means of an IR diode and an IR transistor

to transfer dose size, insulin type, relative time stamp and doser status to the cap unit/medical device (100).

5 The cap/medical device (100) transfers setup data, if any, to the doser (405). The cap/medical device (100) can now calculate the absolute time of this event and transfers it to the electronic log-book.

10 The medical device (100) then searches for a wireless access point (401) to the Internet, and if such a point is found, non-replicated data are transferred from the electronic log-book to a server (403).

15 At 12.30. The user has lunch.

At 13.30. The user decides (optionally the medical device (100) reminds him) to make a control measurement of the glucose content of his blood.

20 The medical device (100) records this event with a time stamp and saves it in the electronic log book. The medical device (100) then searches for a wireless access point (401) to the Internet, and if found, non-replicated data are transferred from the electronic log book to a
25 server (403).

At 17.00. The user decides to measure the glucose content of his blood again.

30 The medical device (100) records this event with a time stamp and saves it in the electronic log book. The medical device (100) then searches for a wireless access point (401) to the Internet, and if found, non-replicated

data are transferred from the electronic logbook to a server (403).

He now decides to take x units of actrapid (making ready
5 for his dinner). After the injection he places his
actrapid doser (405) in the cap/medical device (100).

The doser (405) will now make contact to the cap/medical
device (100) by means of an IR diode and an IR transistor
10 to transfer dose size, insulin type, relative time stamp
and doser status to the cap/medical device (100).

The cap/medical device (100) transfers setup data, if any
to the doser (405). The cap/medical device (100) can now
15 calculate the absolute time of this event and transfers
it to the electronic log book.

The medical device (100) then searches for a wireless
access point (401) to the Internet, and if is found, non-
20 replicated data are transferred from the electronic log
book to a server (403).

At 18.00. The user has his dinner.

25 At 19.00. The user decides (optionally the medical device
(100) reminds him) to make a control measurement of the
glucose content of his blood.

The medical device (100) records this event with a time
30 stamp and saves it in the electronic log book. The
medical device (100) then searches for a wireless access
point (401) to the Internet, and if found, non-replicated
data are transferred from the electronic log book to a
server (403).

At 23.00. The user decides to go to bed. He measures the glucose content of his blood.

5 The medical device (100) records this event with a time stamp and saves it in the electronic log-book. The medical device (100) then searches for a wireless access point (401) to the Internet, and if such a point is found, non-replicated data are transferred from the
10 electronic log-book to a server (403).

He now decides to take x units of insulatard (basic level for the night). He takes another doser (405) which he has already dedicated to be his insulatard doser and injects
15 x units of insulatard. After the injection he places his insulatard doser (405) in/brings within short-range communication range of the cap/medical device (100).

The doser (405) will now make contact to the cap/medical
20 device (100) by means of an IR diode and an IR transistor to transfer dose size, insulin type, relative time stamp and doser status to the cap/medical device (100).

The cap/medical device (100) transfers setup data, if
25 any. to the doser (405). The cap/medical device (100) can now calculate the absolute time of this event and transfers it to the electronic log book.

The medical device (100) then searches for a wireless
30 access point (401) to the Internet, and if found, non-replicated data are transferred from the electronic log book to a server (403).

The user possibly checks whether the medical device (100) contains non-replicated data, and if he finds that it is necessary to connect to his server, he activates a user menu in the medical device (100), which will immediately
5 try to make contact to the server (403).

The medical device (100) then searches for a wireless access point (401) to the Internet, and if such an access point (401) is found, non-replicated data are transferred
10 from the electronic log-book to a server (403).

Figure 5 illustrates the communication between a Bluetooth communication device part and a central Internet server. Shown is a medical device (100) comprising a medical part (101) and a communication part (102) like described earlier. The communication part (102) comprises in this particular embodiment a Bluetooth communication core. The two parts (101; 102) is connected via an Interface Layer of each part so that the critical
15 software, etc. handling the medical related function(s) of the medical device (100) is clearly separated. The medical related function(s) of the medical device (100) is illustrated by an Application Layer. The Interface Layer(s) connects and handles the two asynchronous
20 systems/parts (101; 102) using polling by the medical part (101), assigned as master, of the communication part (102), assigned as a slave. In this way, the communication part (102) may not interfere, interrupt and/or transmit data/information to the medical part
25 (101).
30

A XML Medicom Layer in the medical part (101) is also shown and is responsible for retrieving data/information to be transmitted from the memory of the medical part

(101), calculate a check-sum (e.g. CRC) of the information and format it into a suitable format e.g. a XML format where the information e.g. is formatted into a number of frames each comprising a number of fields.

5

An example of fields in a frame for a given format is:

Name of Data field	Length (chars)	Description
DeviceID	10	10 chars used for unique identification of the medical device.
DeviceVer	4	4 chars used for definition of an actual XML-scheme used.
DeviceTime	12	A timestamp (e.g. mmddyyhhmmss).
FrameCount	10	Indicates FRAME number.
EventType	12	Indicates data type, etc. Note 1
EventTime	12	A timestamp for a given event (e.g. mmddyyhhmmss).
EventSize	4	Value for event (e.g. amount of administered medication or value for measured medical value.
Checksum	8	A calculated check-sum value for the information contained in the frame.

In one example/embodiment events being communicated may be identified by:

10

- Event_Type = INS-S-001 indicates an event where short-acting insulin of type 1 was administered.
- Event_Type = INS-S-XXX indicates an event where short-acting insulin of type 'xxx' was administered.
- 5 Event_Type = INS-L-001 indicates an event where long-acting insulin of type 1 was administered.
- Event_Type = INS-L-YYY indicates an event where long-acting insulin of type 'yyy' was administered.
- 10 Event_Type = INS-M-001 indicates an event where mix-acting insulin of type 1 was administered.
- Event_Type = INS-M-ZZZ indicates an event where mix-acting insulin of type 'zzz' was administered, etc.
- 15 Event_Type = BGM-mmol/l indicates an event where a body fluid measurement/a blood glucose measurement (BGM) is done in mmol/l.
- Event_Type = BGM-mg/dl indicates an event where a body fluid measurement/a blood glucose measurement (BGM) is
- 20 done in mg/dl, etc.
- Event_Type = BGM-mmol/l-k indicates an event where a calibration of a BGM/medical transducer is done in
- 25 mmol/l.
- Event_Type = BGM-mg/dl-k indicates an event where a calibration of a BGM/medical transducer is done in mg/dl, etc.
- 30 Event_Type=STRIPCODE indicates an event where a new strip-code, number identifier, bar-code, etc. for a given type of medication is inputted into the medical device (100).

Each Event_Type has an associated value (if applicable) specifying the actual value associated with the reported event. The range and resolution depends on the given event, e.g. may the values for a given type of medication/insulin cover the values 0 - 999 units (UI) with a resolution of 1/10, a new strip-code may cover the values 0 - 999 with a resolution of 1, a calibration in mg/dl may cover 0 - 999 with a resolution of 1, a calibration in mmol/dl may cover 0 - 99 with a resolution of 1/10, a BGM/body fluid measurement event in mg/dl may cover 0 - 999 with a resolution of 1, a BGM/body fluid measurement event in mmol/dl may cover 0 - 99 with a resolution of 1, etc.

The relevant information/frames is exchanged with the Bluetooth core like described in connection with Figure 3 and transmitted to a Bluetooth supporting communication device/a mobile terminal (401) according to the Bluetooth protocol.

The relevant information/frames is sent via the mobile terminal (401) e.g. using GPRS, as described earlier, via a cell phone provider (502) and the Internet/a network (503) to a database server (403).

Preferably, a firewall (501) is connected between the Internet/the network (503) and the database server (403) in order to enhance the security of the server (403) by prohibiting unauthorised communication. The server (403) may be accessed and may process, transmit and/or receive information like described earlier.

Preferably, the server site also comprises a HTTP server connected between the firewall (501) and the database

server (403) for handling requests from browsers according to the HTTP protocol.

5 The communication between the medical device (100) and the database server (403) may use encryption of communication and the web site (comprising the server(s)) may be secured using HTTPS/SSL (or HTTPS/TLS) communication.

10 The communication between the medical device (100) and the server (403) is preferably substantially a one-way communication (from the device to the server) (although necessary handshakes, receipts, etc. is transferred to the medical device (100)). If applicable, information,
15 e.g. updated data/information, like recommended medical regimes, etc., is also transferred from the server (403) to the medical device (100).

Figure 6a illustrates the short-range communication
20 between a medical device according to the present invention and other medical devices. Shown are a mobile medical device (100), two additional medical devices that in this particular example are two drug administration devices (405) containing different types of medication,
25 e.g. fast- and slow-acting insulin, and a CGM/biosensor (601) like a glucose biosensor.

The dosers (405) comprises input means e.g. a turning wheel (611) for adjusting, either electronically or
30 manually, the level/amount of medication to be administered, activation/input means (616) for initiating the administration of medication and a display (612) that shows the currently selected amount of medication to be administered with text, icons, graphic representations,

etc. The doser (405) preferably has processing means and storage facilities, like a CPU and RAM, for processing and storing data, like the time, date and amount of medication of the last couple of administrations. This
5 information can be shown in the display (612) e.g. on request.

The doser (405) further comprises a cartridge (613) that contains the medication to be administered, and is fitted
10 with a needle (614) through which the medication is administered. The doser (405) has a transparent window (615) so that the amount of medication left in the cartridge (613) can readily be identified.

15 Cartridges (613) may contain different types of insulin, like fast and slow acting insulin, a mix-acting, etc., and the user may insert/exchange a cartridge (613) of a given type when needed and/or use multiple dosers (405) with different types of medication (e.g. fast-acting and
20 slow-acting insulin).

The dosers (405) are also provided with short-range communications means (617) for receiving and transmitting information and data representations from and to other
25 devices as will be described in the following. Alternatively, a doser (405)/an additional medical device (405) may be provided with wireless communications means/a wireless transceiver, as indicated by the arrow in parenthesis, instead or in combination with the short-
30 range communications means (617).

The CGM (601) is a device that monitors/measures the blood glucose level/concentration of a user continuously

and comprises, in this embodiment, a base unit and a glucose biosensor (603).

5 The CGM base unit is in this embodiment the medical device (100) or more specifically the medical device part (101) being in communication with the biosensor (603). Alternatively, a separate CGM base unit may be provided that communicates with the medical device (100).

10 The glucose biosensor (603) is mounted on an adhesive (602) located on an appropriate part of the user's body like the stomach, upper arm, etc. and is located subcutaneous, i.e. in the external fat, in the user's body.

15 The biosensor (603) preferably comprises a potentiostat where a fixed potential can be applied between two electrodes of the biosensor hereby measuring the current that the work electrode of the biosensor produces. The
20 generated current is proportional to the glucose concentration in the blood of the user.

The generated current is transmitted via a wire/cable or wireless communication means like IR transceivers, RF
25 transceivers, etc. to the CGM base unit (100) for a translation/interpretation from a continuous signal into a representation for later processing. Preferably this translation is performed by a standard A/D converter with a sampling rate which at least is faster than the worst
30 case change of the BGL so even the fastest change is 'captured' by the CGM (601)/CGM base unit (100). A sampling rate may e.g. be once every couple of minutes.

Alternatively, the sampling takes place at the biosensor (601) and only the sampled values are transmitted to the CGM base unit (100).

- 5 The converted measurement/continuous values may be presented to the user via displaying means (606) like a LCD display, etc.

10 The converted measurements are kept in a memory for later retrieval, analysis, and etc. so a detailed history log of sampled measurements may be obtained. This detailed history log may e.g. be used to predict a trend for the BGL of a user thereby enhancing the information value for the user.

15

In one embodiment the BGL measurement is converted into a corresponding amount of insulin needed to bring the user into compliance and displayed on the display (606).

- 20 The biosensor (603) is preferably calibrated on a regular basis, e.g. each day, by external calibration e.g. by a traditional blood glucose monitor (BGM) system, in order to ensure the best accuracy. Typically the biosensor (603) will have to be replaced after e.g. three days of
25 use and be calibrated once each day.

Alternatively, the CGM may be embodied by other invasive, semi-invasive or non-invasive systems.

- 30 In a preferred embodiment, the medical device (100) is a protective cap unit comprising an integrated blood glucose monitor (BGM), and one additional medical device (405) is an insulin administration device arranged so that they automatically transmit, via short-range

communications means, relevant data information between them when the devices are mutually positioned in a suitable communication position, e.g. when the cap unit/the medical device (100) is fitted onto, docked with/onto, clicked-on, screwed-into, snapped-with, etc. with the additional medication device (405).

Alternatively, the additional medication device (405) may be another type of drug administration device like a pen, syringe, inhaler, tablet dispenser, etc. or in general any medication administration device.

In this way, simplicity for the user is obtained, since the devices automatically store and exchange data information as part of the normal use.

The cap unit/medical device (100) can be fitted to an additional medication device (405) so that one single compact unit and protection of the additional medication device (405) is obtained.

In this way, the user does not have to worry about collecting data information in a separate log-book and additionally, the data information may be collected in a single apparatus for further processing, transmission and/or use. In this way, a complete log-book is obtained in e.g. a single device, which may be used by the user with the help of the devices to obtain detailed information of trends, current and/or previous state(s), re-occurring events, e.g. that adverse effects relating to the self-treatment occur every Sunday by using/analysing for behavioural and/or measured physiological patterns.

The short-range communications means (617) is preferably an infrared (IR) communications means/transceiver providing IR communication of data information between the medical device (100) and the additional medication
5 device (405).

Alternatively, the short-range communications means (617) is an inductive means i.e. comprising inductive coils or the like in each device.
10

As another alternative, the short-range communications (617) is a electrical communications means, i.e. a simple switch mechanism that may be used to transfer data information between devices.
15

The embodiments of the short-range communication means (617') are explained in greater detail in connection with Figures 7a - 7c.

20 Additionally, the energy/power used for communication between the apparatuses is minimized and/or reduced since only (very) short-range communication needs to be used when the cap/medical device (100) is fitted on, etc. to the additional medication device (405). This is very
25 important, especially for portable apparatuses, since reduced energy consumption extends the time between the need for charging a power source of the apparatuses, like a battery, etc., prolongs the time where the apparatuses may be used and/or extends the life-time of a non-
30 chargeable power source.

Figure 6b illustrates communication between a medical device according to the present invention and other medical devices. Shown are a medical device (100)

according to the present invention, a CGM biosensor (601), a drug administration device (405), a schematic representation of additional medical device(s) (405), and a general base unit (620).

5

The general base unit (620) comprises a display (621), a user interface and, preferably, wireless communication means/a wireless transceiver for collecting and/or exchange relevant data information from the other devices (601, 405). The information may be viewed at the display (621) and stored at the base unit (620) and be transmitted to the medical device (100) using short-range communication means (617) when docking, fitting, clicking-on, screw-into, snap-with, etc. the medical device (100) and the base unit (620), as described earlier. Alternatively, the base unit (620) and the medical device (100) is provided with wireless communications means/a transceiver instead or in addition to the short-range means (617), as indicated by the arrow in parenthesis.

20

The additional medical device(s) (405) may comprise a tablet dispenser, inhaler, a balance, body fluid measure device, drug administration device or in general other diabetes relevant data sources.

25

In this way, an easy way of obtaining additional information from various other relevant devices is provided.

30

Figures 7a - 7c illustrate examples of various embodiments of the short-range communication means.

Figure 7a illustrates an embodiment of the short-range communication means adapted to communicate optically. Shown is an example of an embodiment of infrared (IR) communication means/transceivers. Shown are a receiver part (701) of the medical device part and a transmitter part (702) of an additional medical device. Alternatively, the medical device part and additional medical device is each provided with a receiver (701) and a transmitter (702) thereby enabling two-way communication.

Figure 7b illustrates an embodiment of the short-range communication means adapted to communicate via an electrical switch. Shown is a cross-sectional view of an example of an embodiment of simple mechanical/electrical communication means in the form of switches. Shown are the communication switches of a medical device part (701) and of an additional medical device (702). The communications switches (703; 703') of the medical part (701) have an electric connection between them when the medical device part and additional device (701; 702) is not docked, fitted onto, in an interrelated communication position, etc. When the two devices (701; 702) are brought together then a first switch/switch part (704) of the additional device (702) touches and moves the first switch/switch part (703) of the medical device part (701) thereby establishing an electronic connection between them (703, 704) and breaking the connection of switch/switch part (703) and (703'). During the same movement a second switch/switch part (704') of the additional device (702) touches the second switch/switch part (703') of the medical device part (701) thereby establishing an electronic connection. The breaking of the connection between the first switch/switch part (703)

and the second switch/switch part (703') may determine when communication, transfer of information, etc. may be initiated.

- 5 The first (704) and second switch/switch part (704') of the second apparatus is preferably separated by an insulation layer (705).

10 Figure 7c illustrates an embodiment of the short-range communication means adapted to communicate via inductive communication. Shown is an example of an embodiment of simple inductive communication means where current induced in a resonance circuit is used to transfer information. Shown are a receiver part (701) of a medical
15 device part and a transmitter part (702) of an additional medical device. Alternatively, the medical device part and the additional medical device is each provided with a receiver (701) and a transmitter (702) thereby enabling two-way communication.

P a t e n t C l a i m s :

1. A portable medical device (100) for communication of
5 medical data information comprising
- a medical device part (101)
 - o comprising a first processor (104) and first storage means (103), and
 - o means (106) for executing one or more medical
10 related functions,
 - a communication device part (102)
 - o comprising a second processor (104'), second storage means (103'), and
 - o communication means (105),
- 15 where the medical device part (101) and the communication device part (102) is connected allowing for exchange of data information according to a predetermined protocol, the exchange of data information is under the control of the medical device part (101) and where the
20 functionalities of each device part otherwise is separated.
2. A device according to claim 1, c h a r a c t e r i z e d in that the predetermined protocol comprises the
25 medical device part (101) acting as a master and the communication device part (102) acting as a slave where the exchange of information is done by the medical device part (101) polling the communication device part (102).
- 30 3. A device according to claims 1 - 2, c h a r a c t e r i z e d in that the medical device part (102) further comprises one or more of:
- a user interface (201; 202),
 - at least one medical transducer (106)

- discrete and/or substantially continuously body fluid analysis means (106),
- drug administration means (106), and
- a short-range communication means (106') for
5 exchanging data information with at least another medical device (405).

4. A device according to claim 3, c h a r a c t e r i z e d in that the at least another medical device (405) is
10 selected from the group of:

- a drug administration device (405),
- a body fluid analyser (405),
- an insulin administration device (405),
- a blood glucose monitor (BGM) (405; 601),
- 15 • a continuous blood glucose monitor (CGM) (405; 601),
- an inhaler (405),
- a tablet dispenser (405),
- a lipid monitor (405),
- a pulse monitor (405),
- 20 • a lancet device (405),
- a storage container (405),
- a balance (405),
- and any other apparatus (405) adapted to measure at least one physiological parameter.

25

5. A device according to claims 1 - 4, c h a r a c t e r i z e d in that the device further comprises a power supply (203) supplying the communication device part (102) with power where the power supply may be turned on
30 and off under the control of the medical device part (101).

6. A device according to claims 1 - 5, c h a r a c t e r i z e d in that said communication means (105) is

adapted to communicate according to the Bluetooth protocol.

7. A device according to claims 1 - 6, c h a r a c t e r i z e d in that said communication means (105) are adapted to communicate information according to one or more of:

- Radio frequency (RF) communication,
- Infrared (IR) communication,
- 10 • HTTP (Hyper Text Transmission Protocol),
- SHTTP (Secure Hyper Text Transmission Protocol),
- TCP/IP (Transmission Control Protocol/Internet Protocol),
- PPP (Point-to-Point),
- 15 • SSL (Secure Socket Layer),
- TLS (Transport Layer Security), and
- IrDA,

8. A device according to claims 1 - 7, c h a r a c t e r i z e d in that said communication means (105) are adapted to communicate with a wireless access point/a mobile terminal (401) where the access point/the terminal (401) is adapted to communicate according to one or more of:

- 25 • GSM (Global System for Mobile communication),
- GPRS (General Packet Radio System), and
- UMTS (Universal Mobile Telephone System).

9. A device according to claims 1 - 8, c h a r a c t e r i z e d in that the communication device part (101) is adapted to exchange data information with a central server (403) via a wireless network access point (401).

10. System for supplying data from a portable medical device (100) to a third party, where the system is adapted to

- 5 • automatically transmit data information from a portable medical device (100) to a central server (403) for storage in at least one database,
- process said data information, in order to derive additional information, and
- 10 • automatically transmit at least a part of the additional information to a predetermined third party.

11. System according to claim 10, c h a r a c t e r i z e d in that said processing is done at said server (403)
15 and/or at said medical device (100).

12. System according to claims 10 - 11, c h a r a c t e r i z e d in that said data information comprises information representing one or more of:

- 20 • at least one blood glucose value,
- at least one value representing a body fluid level,
- at least one physiological parameter,
- amount and/or type of administered medication,
- amount and/or type of administered insulin,
- 25 • a trend of a glucose or body fluid level,
- a prediction of a glucose or body fluid level,
- timestamp in- or excluding date,
- amount of food,
- measurement of physical activity,
- 30 • notification of appointment,
- inventory logistics, and
- body characteristics.
- warnings, and
- symptoms.

13. System according to claims 10 - 12, c h a r a c t e r
i z e d in that the system is adapted to transmit data
information from a portable medical device (100) to a
5 central server (403) according to the Bluetooth protocol
to a wireless access point (401) connected via a network
(503) to the central server (403).

14. System according to claims 10 - 13, c h a r a c t e r
10 i z e d in that said third parties are one or more of:
• at least one relative,
• at least one parent, and
• at least one medical professional.

15 15. System according to claims 10 - 14, c h a r a c t e r
i z e d in that the system is further adapted to
• exchange information between the portable medical
device (100) and another medical device (405) in
order to retrieve relevant data information.

20

16. System for collecting data information from a number
of portable devices (100), where the system is adapted
to:

- 25 • generate data information in a portable device
(100), the data information relating to a clinical
trial of a medical device and/or medical product,
- automatically sending the data information from the
portable device (100) to a central server (403) for
storage in a database,
- 30 • process said data information.

17. A method of communication of medical data information
between a medical device part (101)

o comprising a first processor (104) and first storage means (103), and
o means (106) for executing one or more medical related functions,
5 and a communication device part (102)
o comprising a second processor (104'), second storage means (103'), and
o communication means (105),
where the medical device part (101) and the communication
10 device part (102) exchanges data information according to a predetermined protocol, the exchange of data information is under the control of the medical device part (101) and where the functionalities of each device part otherwise is separated.

15

18. A method according to claim 17, c h a r a c t e r i z e d in that the predetermined protocol comprises the medical device part (101) acting as a master and the communication device part (102) acting as a slave where
20 the exchange of information is done by the medical device part (101) polling the communication device part (102).

19. A method according to claims 17 - 18, c h a r a c t e r i z e d in that the medical device part (102) further
25 comprises one or more of:

- a user interface (201; 202),
- at least one medical transducer (106)
- discrete and/or substantially continuously body fluid analysis means (106),
30 • drug administration means (106), and
- a short-range communication means (106') for exchanging data information with at least another medical device (405).

20. A method according to claim 19, c h a r a c t e r i z e d in that the at least another medical device (405) is selected from the group of:

- a drug administration device (405),
- 5 • a body fluid analyser (405),
- an insulin administration device (405),
- a blood glucose monitor (BGM) (405; 601),
- a continuous blood glucose monitor (CGM) (405; 601),
- an inhaler (405),
- 10 • a tablet dispenser (405),
- a lipid monitor (405),
- a pulse monitor (405),
- a lancet device (405),
- a storage container (405),
- 15 • a balance (405),
- and any other apparatus (405) adapted to measure at least one physiological parameter.

21. A method according to claims 17 - 20, c h a r a c t e r i z e d in that the method further comprises controlling a power supply (203) by the medical device part (101), where the power supply supplies the communication device part (102) with power.

22. A method according to claims 17 - 21, c h a r a c t e r i z e d in that said communication means (105) communicates according to the Bluetooth protocol.

23. A method according to claims 17 - 22, c h a r a c t e r i z e d in that said communication means (105) communicates information according to one or more of:

- Radio frequency (RF) communication,
- Infrared (IR) communication,
- HTTP (Hyper Text Transmission Protocol),

- SHTTP (Secure Hyper Text Transmission Protocol),
- TCP/IP (Transmission Control Protocol/Internet Protocol),
- PPP (Point-to-Point),
- 5 • SSL (Secure Socket Layer),
- TLS (Transport Layer Security), and
- IrDA,

24. A method according to claims 17 - 23, c h a r a c t e
10 r i z e d in that said communication means (105)
communicates with a wireless access point/a mobile
terminal (401) where the access point/the terminal (401)
communicates according to one or more of:

- GSM (Global System for Mobile communication),
- 15 • GPRS (General Packet Radio System), and
- UMTS (Universal Mobile Telephone System).

25. A method according to claims 17 - 14, c h a r a c t e
r i z e d in that the communication device part (101)
20 exchanges data information with a central server (403)
via a wireless network access point (401).

26. Method of supplying data from a portable medical
device (100) to a third party, the method comprising the
25 steps of:

- automatically transmitting data information from a
portable medical device (100) to a central server
(403) for storage in at least one database,
- processing said data information, in order to derive
30 additional information, and
- automatically transmitting at least a part of the
additional information to a predetermined third
party (402; 404).

27. Method according to claim 26, c h a r a c t e r i z e d in that said processing is done at said server (403) and/or at said medical device (100).

- 5 28. Method according to claims 26 - 27, c h a r a c t e r i z e d in that said data information comprises information representing one or more of:
- at least one blood glucose value,
 - at least one value representing a body fluid level,
 - 10 • at least one physiological parameter,
 - amount and/or type of administered medication,
 - amount and/or type of administered insulin,
 - a trend of a glucose or body fluid level,
 - a prediction of a glucose or body fluid level,
 - 15 • timestamp in- or excluding date,
 - amount of food,
 - measurement of physical activity,
 - notification of appointment,
 - inventory logistics, and
 - 20 • body characteristics.
 - warnings, and
 - symptoms.

29. Method according to claims 26 - 28, c h a r a c t e r i z e d in that said step of transmitting data information from a portable medical device (100) to a central server (403) is done by transmitting said data information according to the Bluetooth protocol to a wireless access point (401) connected via a network (503) to the central server (403).

25

30

30. Method according to claims 26 - 29, c h a r a c t e r i z e d in that said third parties (402; 404) are one or more of:

- at least one relative,
- at least one parent, and
- at least one medical professional.

5 31. Method according to claims 26 - 30, c h a r a c t e r
i z e d in that said method further comprises the step
of:

- communicating between the portable medical device
(100) and another medical device (405) in order to
10 retrieve relevant data information.

32. Method of collecting data information from a number
of portable devices (100; 405; 601;), the method
comprising the steps of:

- 15 • generating data information in a portable device
(100; 405; 601), the data information relating to a
clinical trial of a predetermined medical product
and/or device,
- automatically sending the data information from the
20 portable device (100) to a central server (403) for
storage in a database,
- processing said data information.
